

41
[(2,3) share] and a common memory means shared by the first and second functional units [(11)], the data processing device being programmed for executing an instruction by the first functional unit [(2)], [the] execution of said instruction involving input/output operations by the first functional unit [(2)], wherein said execution involves at least one of: output data of the first functional unit [(2) is] being processed by the second functional unit [(3)] [during] in the midst of execution of said instruction [execution], and[/or the] input data to the first functional unit being [is] generated by the second functional [(3)] unit [during] in the midst of execution of said instruction [execution].

2. (Currently amended) The data [Data] processing device according to claim 1, [characterized in that] wherein the first functional unit [(2)] is arranged for processing instructions of a first type corresponding to operations having a relatively large latency and [in that] the second functional unit [(3)] is arranged for processing instructions of a second type corresponding to operations having a relatively small latency.
3. (Currently amended) The data [Data] processing device according to claim 1, having halt means controllable by the master controller for suspending operation of the first functional unit [(2)].
4. (Currently amended) A method of operating a [dataprocessor] data processing device, [which device comprises at least] comprising:

M
a master controller [(1)] for controlling operation of the data processing device,

a first functional unit [(2)], which includes a slave controller [(20)], the first functional unit [(2)] being arranged for executing instructions of a first type corresponding to operations having a relatively long latency,

a second functional unit [(3)] capable of executing instructions of a second type corresponding to operations having a relatively short latency, wherein the first functional unit [(2)] during execution of an instruction of the first type receives input data and provides output data, and said execution involves at least one of: [according to which method the] output data [is] of the first functional unit being processed by the second functional unit [(3) during] in the midst of execution of said instruction [execution], and/or the] input data [is] to the first functional unit being generated by the second functional unit [(3) during] in the midst of execution of said instruction [execution].

5. (Currently amended) The method [Method] according to claim 4, [characterized in that,] wherein the master controller [(1)] temporarily suspends operation of the first functional unit [(2)] during execution of instructions of the first type.
6. (Currently amended) A method for compiling a program into a sequence of instructions for operating a processing device comprising a master controller, a first functional unit including a slave controller, a second functional unit, and a

common memory means shared by the first and second functional units, the method comprising: [according to which method]

composing a model [is composed] which is representative of [the] input/output operations involved in the execution of an instruction [instructions] by [a] the first functional unit [(2)],

on the basis of this model, scheduling instructions for the [one or more] second functional unit [units (3) are scheduled] for performing at least one of: providing input data for the first functional unit [(2)] when [it] the first functional unit is in the midst of executing an instruction in which said input data is used, and[or for] retrieving output data from the first functional unit [(2)] when [it] the first functional unit is in the midst of executing an instruction in which said output data is computed.

7. (Currently amended) [A] The method according to claim 6, [characterized in that] wherein the model is a signal flow graph.
